

**FOCUS RING ARRANGEMENT FOR SUBSTANTIALLY ELIMINATING  
UNCONFINED PLASMA IN A PLASMA PROCESSING CHAMBER**

5 **By Inventor**

Eric H. Lenz

**BACKGROUND OF THE INVENTION**

10 The present invention relates to the manufacture of semiconductor-based products. More particularly, the present invention relates to improved techniques for controlling plasma formation in a plasma processing chamber.

The use of plasma-enhanced processes in the manufacture of semiconductor-based products (such as integrated circuits or flat panel displays) is well known.

15 Generally speaking, plasma-enhanced processes involve the processing of a substrate (e.g., a glass panel or a semiconductor wafer) in a plasma processing chamber. Within the plasma processing chamber, a plasma may be ignited out of appropriate etchant or deposition source gases to respectively etch or deposit a layer of material on the surface of the substrate.

20 To facilitate discussion, Fig. 1 depicts a capacitively-coupled plasma processing chamber 100, representing an exemplary plasma processing chamber of the types typically employed to etch a substrate. Referring now to Fig. 1, there is shown a chuck 104, representing the workpiece holder on which a substrate 106 is positioned during etching. Chuck 104 may be implemented by any suitable chucking technique, e.g., electrostatic, mechanical, clamping, vacuum, or the like. During etching, chuck 25 104 is typically supplied with RF power having a frequency of, for example, about 2 MHz to about 27 MHz, by an RF power supply 110. In some systems, chuck 104 may be supplied with dual frequencies, e.g., 2MHz and 27MHz simultaneously during etching.

*6, 24, 99*

Above substrate 106, there is disposed a reactor top 112, which is formed of a conductive material such as aluminum. Confinement rings 102 may be coupled in a fixed manner to ~~reactor top 112~~ or may be coupled to cam-based plungers (not shown in Fig. 1) that allow confinement rings 102 to be raised and lowered without moving reactor top 112. Further details pertaining to the cam-based arrangement may be found in a co-pending U.S. patent application <sup>N. 01/04, 158</sup> entitled "Cam-based Arrangement for Positioning Confinement Rings in a Plasma Processing Chamber," filed on even date by inventor Eric H. Lenz (Attorney Docket No. P398/LAM1P088) and incorporated by reference herein.

10 In general, confinement rings 102 help confine the etching plasma to the region above substrate 106 to improve process control and to ensure repeatability. Although only two confinement rings are shown in the example of Fig. 1, it should be understood that any number of confinement rings may be provided. Confinement rings and their function may be better understood by reference to commonly assigned 15 U.S. Patent No. 5,534,751, which is incorporated by reference herein.

Also coupled to reactor top 112 are an upper electrode 114 and a baffle 116. Upper electrode 114 may be grounded (as in the case of Fig. 1) or may be powered by another ~~RF power source 120~~ during etching. If upper electrode 114 is powered, it may be insulated from the remainder of the reactor to isolate the electrode from ground. 20 During etching, plasma is formed from etchant source gas supplied via a gas line 122 and baffle 116. .

When RF power is supplied to chuck 104 (from radio frequency generator 110), equipotential field lines are set up over substrate 106. During plasma processing, the positive ions accelerate across the equipotential field lines to impinge 25 on the surface of substrate 106, thereby providing the desired etch effect (such as improving etch directionality). Due to geometry factors, however, the field lines may not be uniform across the substrate surface and may vary significantly at the edge of substrate 106. Accordingly, a focus ring is typically provided to improve process uniformity across the entire substrate surface. With reference to Fig. 1, chuck 104 is 30 shown disposed within a focus ring 108, which is typically formed of a suitable dielectric material such as ceramic, quartz, or plastic.

The equipotential field lines that are set up during plasma etching may be seen more clearly in Fig. 2. In Fig. 2, the presence of focus ring 108 allow the equipotential field lines to be disposed substantially uniformly over the entire surface of the substrate, thereby allowing etching to proceed in a uniform manner across the substrate. As seen by Fig. 2, however, some of the equipotential field lines also extend into the region 160 outside of focus ring 108. The presence of the equipotential field lines in region 160 may cause any charged particles that leak past the confinement rings to accelerate in a direction perpendicular to the equipotential field lines toward the chamber walls. This acceleration and the subsequent collision between the charged particles and the chamber walls may generate secondary electrons, which may ignite and/or sustain unconfined plasma in region 160 (i.e., unintended plasma that is not confined to region directly above the substrate).

The inadvertent generation of plasma in region 160 renders the etch process difficult to control and may damage components within this region. By way of example, this unconfined plasma, which may be unplanned and/or intermittent, changes the amount of power absorbed by the plasma within the plasma processing chamber, thereby making it difficult to control the delivery of power to the chuck to achieve consistent, repeatable etch results. As another example, the presence of unwanted plasma in region 160 may cause damage to the chamber door, particularly to the seals that are provided therewith. The chamber door is necessary for substrate transport into and out of the chamber, and if the seals are damaged, accurate control of the chamber pressure may be difficult. When the seals and/or other components in region 160 are inadvertently attacked by the plasma, particulate and/or polymeric contaminants may form along the chamber walls, potentially leading to contamination of the etch environment.

In view of the foregoing, there are desired techniques for minimizing and/or eliminating the unwanted plasma formation in the region outside of the focus ring of the plasma processing chamber.

## SUMMARY OF THE INVENTION

The invention relates, in one embodiment, to a focus ring assembly configured  
5 to substantially encircle a chuck of a plasma processing chamber. The focus ring  
assembly includes an annular dielectric body; and an electrically conductive shield  
surrounding the annular dielectric body. The electrically conductive shield is  
configured to be electrically grounded within the plasma processing chamber and  
includes a tube-shaped portion being disposed outside of the annular dielectric body  
10 and surrounding at least part of the annular dielectric body. The electrically  
conductive shield further includes an inwardly-protruding flange portion being in  
electrical contact with the tube-shaped portion. The flange portion forms a plane that  
intersects the tube-shaped portion. The flange portion is embedded within the annular  
dielectric body.

15

In another embodiment, the invention relates to a plasma processing chamber  
configured to process a substrate. The plasma processing system includes a chuck  
configured to support the substrate during plasma processing. There is further  
included a focus ring assembly substantially encircling the chuck. The focus ring  
20 assembly includes an annular dielectric body and an electrically conductive shield  
surrounding the annular dielectric body. The electrically conductive shield is  
configured to be electrically grounded within the plasma processing chamber. The  
electrically conductive shield includes a tube-shaped portion being disposed outside of  
the annular dielectric body and surrounding at least part of the annular dielectric body.  
25 The electrically conductive shield further includes an inwardly-protruding flange  
portion being in electrical contact with the tube-shaped portion. The flange portion  
forms a plane that intersects the tube-shaped portion. The flange portion is embedded  
within the annular dielectric body.

30

In yet another embodiment, the invention relates to a method for forming a  
focus ring assembly of a plasma processing chamber. The focus ring assembly is  
configured to substantially encircle a chuck of the plasma processing chamber. The

method includes providing an annular dielectric body and surrounding the annular dielectric body with an electrically conductive shield, which includes surrounding at least part of the annular dielectric body with a tube-shaped portion of the electrically conductive shield. The tube-shaped portion is disposed outside of the annular dielectric body. The surrounding the annular dielectric body with an electrically conductive shield includes embedding an inwardly-protruding flange portion of the electrically conductive shield within the annular dielectric body. The inwardly-protruding flange portion is in electrical contact with the tube-shaped portion. The flange portion forms a plane that intersects the tube-shaped portion.

10 These and other features of the present invention will be described in more detail below in the detailed description of the invention and in conjunction with the following figures.

### BRIEF DESCRIPTION OF THE DRAWINGS

The present invention is illustrated by way of example, and not by way of limitation, in the figures of the accompanying drawings, which are not drawn to scale to simplify the illustration and in which like reference numerals refer to similar elements.

Fig. 1 illustrates a typical capacitively coupled plasma processing chamber.

Fig. 2 illustrates the equipotential field lines that may be formed in the plasma processing chamber of Fig. 1 during plasma processing.

10 Fig. 3 illustrates, in accordance with one embodiment of the present invention, the inventive focus ring assembly, including a grounded electrically conductive shield having both a tube-shaped portion and an inwardly-protruding flange portion.

Fig. 4 illustrates the field lines that may be formed when the inwardly-protruding flange portion of the grounded electrically conductive shield is omitted.

## DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention will now be described in detail with reference to a few preferred embodiments thereof as illustrated in the accompanying drawings.

5 In the following description, numerous specific details are set forth in order to provide a thorough understanding of the present invention. It will be apparent, however, to one skilled in the art, that the present invention may be practiced without some or all of these specific details. In other instances, well known process steps and/or structures have not been described in detail in order to not 10 unnecessarily obscure the present invention.

In accordance with one aspect of the present invention, process control is substantially improved by reducing or eliminating the unconfined plasma (i.e., the unwanted plasma that is inadvertently ignited and/or sustained outside of the focus ring). As the term is employed herein, the region outside of the focus ring refers to 15 annular region of the plasma processing chamber which is external to the column of space whose outer periphery is defined by the circumference of the focus ring. The plasma is preferably confined within this column of space. Outside of the focus ring, the electric field is preferably reduced to the point where plasma can no longer be sustained. By eliminating the unconfined plasma, the amount of power absorbed by 20 the etching plasma that is disposed above the substrate may be more consistent from substrate to substrate, thereby rendering the etch repeatable. The elimination of the unconfined plasma also helps reduce the corrosion or break down of components disposed in the region outside of the focus ring (e.g., door seals).

In accordance with one embodiment of the present invention, there is provided 25 a focus ring assembly, including a grounded conductive shield which is configured to concentrate the equipotential field lines in the focus ring body. The grounded conductive shield preferably includes two portions: a tube-shaped portion which surrounds at least a part of the dielectric focus ring body and an inwardly-protruding flange portion which is embedded within the dielectric focus ring body itself. It is 30 believed that this configuration substantially reduces the density of equipotential field

lines in the region outside of the focus ring. By substantially reducing the density of equipotential field lines in the near-vacuum region outside of the focus ring, the amount of energy acquired by any charged particle that leaks into this area is substantially reduced, thereby essentially eliminating the possibility of plasma ignition and/or sustenance.

The features and advantages of the present invention may be better understood with reference to the figures that follow. Fig. 3 illustrates a relevant portion of the plasma processing chamber of Fig. 1, including a focus ring assembly 300. As shown in Fig. 3, focus ring assembly 300 includes an annular dielectric body 302 (including both portions 302(a) and 302(b)), which encircles chuck 104 when viewed from above. Annular dielectric body 302 may be formed of a suitable dielectric material such as quartz, alumina, silicon nitride, or a plastic material such as <sup>TEFLON™</sup> ~~Teflon™~~, polyimid, polyetheretherketone (PEEK), polyamid, polyimidamid, VESPEL™ or the like.

As will be discussed later herein, annular dielectric body 302 may also be a composite structure that may include two or more different portions, each of which may be formed of a different dielectric material.

Focus ring assembly 300 also includes an electrically conductive shield 304, which comprises a tube-shaped portion 304(a) and an inwardly-protruding portion 304(b), which is in electrical contact with tube-shaped portion 304(a). As seen in Fig. 3, tube-shaped portion 304(a) substantially surrounds and shields the lower portion of annular dielectric body 302 while inwardly-protruding portion 304(b) is embedded within annular dielectric body 302 itself. It is believed that the presence of inwardly-protruding portion 304(b), which is grounded during operation, substantially reduces the density of the equipotential field lines in the upper portion of annular region 306, i.e., the region outside of the focus ring.

While not wishing to be bound by theory, it is believed that inwardly-protruding portion 304(b) forces the equipotential lines to curve sharply away from region 306 in order to stay in between high voltage chuck 104 and the ground potential, which is present on electrically conductive shield 304 during operation. If

inwardly-protruding portion 304(b) were absent from the electrically conductive shield, it is believed that some of the equipotential field lines may extend into region 306, particularly into the upper portion of region 306, to energize ions in region 306 and possibly ignite new plasma or sustain plasma already existing therein.

5 With reference to Fig. 4, for example, the electrically conductive shield is shown having only a tube-shaped portion (i.e., without an inwardly-protruding portion). In Fig. 4, some of the field lines are shown extending into the upper portion of region 306. Because of this, there is potentially sufficient electric field density in this region to ignite and/or sustain the unwanted plasma.

10 Note that it is disadvantageous to extend the tube-shaped portion upward beyond the upper surface of the annular dielectric body of focus ring 302 since the presence of a physical structure, such as an extended tube-shaped conductive shield, in the upper portion of region 306 may impede substrate transport and/or byproduct exhaust. While it is possible that some arrangement may be provided to move such an 15 extended conductive shield out of the way for substrate transport, the additional complexity and expenses involved therewith would have been undesirable. Also, such an extended conductive shield may be corroded by undue contact with the plasma byproducts.

20 It should be appreciated that it may also be disadvantageous and/or impractical to fill up a portion or all of region 306 with a dielectric material simply for the purpose of minimizing or eliminating the near-vacuum region in which plasma may be formed. At least a portion of region 306 may, in any case, need to remain unobstructed to serve as part of the exhaust path through which the etch byproducts may be pumped away. Accordingly, the use of the inwardly-protruding flange portion 25 (as is done in the embodiment of Fig. 3) to force the equipotential field lines to curve sharply away from region 306 advantageously reduces and/or eliminates unconfined plasma formation without the disadvantages associated with extending the tube-shaped portion into the upper portion of region 306 (which may block the substrate transport path or the exhaust path) or without the disadvantages associated with filling 30 region 306 (which interferes with the exhaust operation).

Although inwardly-protruding flange portion 304(b) is shown forming a 90° angle with the longitudinal axis of tube-shaped portion 304(a) of the electrically conductive shield in Fig. 3, the exact angle at which these two portions intersect is not critical. Likewise, even though inwardly-protruding flange portion 304(b) is shown connected to the upper edge of tube-shaped portion 304(a), it is contemplated that this connection may be made lower or higher relative to the upper edge of tube-shaped portion 304(a). Also, the exact depth of penetration of inwardly-protruding flange portion 304(b) into the body of the focus ring may also vary from system to system. It is of course preferable that the inwardly-protruding flange portion 304(b) protrudes sufficiently into the body of the focus ring to bend a sufficient number of equipotential field lines away from region 306 and reduce the electric field density in this region to a sufficiently low level such that unconfined plasma cannot be ignited and/or sustained.

Additionally, although inwardly-protruding flange portion 304(b) is shown integrally formed with tube-shaped portion 304(a) in Fig. 3, such is not absolutely necessary. For example, it is contemplated that inwardly-protruding flange portion 304(b) may be a separately formed electrically conductive piece that is in electrical contact with tube-shaped portion 304(a) and ground. As such, inwardly-protruding flange portion 304(b) would also serve its purpose of bending the equipotential field lines sharply away from region 306 so that unconfined plasma in this region cannot be formed and/or sustained.

In Fig. 3, tube-shaped portion 304(a) is shown disposed outside of the annular dielectric body of the focus ring. By spacing the tube-shaped portion 304(a) (which is grounded during operation) as far away from high voltage chuck 104 as possible, arcing across the gap between the high voltage chuck and the inner surface of the focus ring is substantially minimized, which advantageously prolongs the life of the focus ring and/or the high voltage chuck.

In one optional embodiment, annular dielectric body 302 may represent a composite structure, which includes two or more different portions. With reference to Fig. 3, for example, this refinement is shown by the presence of both first annular dielectric portion 302(a) and second annular dielectric portion 302(b). First annular

dielectric portion 302(a) may be formed of, for example, a ceramic material to maximize resistance to the etching effects of the plasma and to provide structural rigidity and stability with changing temperature. It is contemplated, however, that first annular dielectric portion 302(a) may be formed of any suitable dielectric  
5 material such as quartz, alumina, silicon nitride, or a plastic material such as polyimid, polyetheretherketone (PEEK), polyamid, polyimidamid, VESPEL™ or the like.

Second annular dielectric portion 302(b) may be formed of, for example, a plastic material such as Teflon™, which is closer in dielectric constant to vacuum than the dielectric material of first annular dielectric portion 302(a). It is  
10 contemplated, however, that first annular dielectric portion 302(a) may also be formed of any suitable dielectric material such as quartz, alumina, silicon nitride, or a plastic material such as polyimid, polyetheretherketone (PEEK), polyamid, polyimidamid, VESPEL™ or the like. In any case, the use of a dielectric material that has a dielectric constant close to the dielectric constant of vacuum for second annular  
15 dielectric portion 302(b) advantageously reduces electrical stress within the focus ring arrangement.

To elaborate, electrical stress may be created if second annular dielectric portion 302(b) is formed of a material having a high dielectric constant, and there is a small vacuum gap between tube-shaped portion 304(a) and second annular dielectric portion 302(b) (due to, for example, manufacturing tolerance) since most of the field lines would be concentrated in the small vacuum gap. By using a material having a dielectric constant close to the dielectric constant of vacuum for second annular dielectric portion 302(b), the field lines are more equally spread throughout the thickness between tube-shaped portion 304(a) and the inner wall of second annular dielectric portion 302(b), which helps reduce electrical stress and prolong the useful  
25 life of the focus ring arrangement.

By forming the annular dielectric body in two or more separate portions, the embedding of inwardly-protruding flange portion 304(b) into the annular dielectric body is also simplified. By way of example, such embedding may be accomplished  
30 simply by inserting the inwardly-protruding flange portion into the space between first annular dielectric portion 302(a) and second annular dielectric portion 302(b) of Fig.

3. Accordingly, it is not necessary to mold the annular dielectric body around the electrically conductive shield in order to embed the inwardly-protruding flange portion into the annular dielectric body. Further, if adjustments need to be made to the position of the annular dielectric body relative to the chuck (in order to calibrate a system, for example), the use of a multi-portion annular dielectric body also helps simplify the adjustment. By way of example, adjustment may be made simply by raising or lowering first annular dielectric portion 302(a) without disturbing the rest of the focus ring arrangement.

While this invention has been described in terms of several preferred embodiments, there are alterations, permutations, and equivalents which fall within the scope of this invention. By way of example, although the plasma processing system employed to illustrate the invention utilizes confinement rings, those confinement rings are not absolutely required. Although the presence of the confinement rings helps in reducing the amount of charged ions leaked outside of the region immediately above the substrate, the use of the inventive focus ring arrangement, which includes a conductive ground shield having an inwardly-protruding flange, also advantageously reduces unconfined plasma formation and/or sustenance even when confinement rings are not provided. Further, although a capacitively coupled plasma processing chamber is employed herein to facilitate discussion of the preferred embodiment, it is contemplated that the inventive focus ring assembly may also be beneficial to etch processes performed in other types of plasma processing systems (e.g., inductively coupled plasma processing systems, ECR-based systems, MORI source-based systems, and the like). It should also be noted that there are may alternative ways of implementing the methods and apparatuses of the present invention. It is therefore intended that the following appended claims be interpreted as including all such alterations, permutations, and equivalents as fall within the true spirit and scope of the present invention.
